

Stacks and Queues

Stacks and Queues

- A **stack** is a last in, first out (**LIFO**) data structure
 - Items are removed from a stack in the reverse order from the way they were inserted
- A **queue** is a first in, first out (**FIFO**) data structure
 - Items are removed from a queue in the same order as they were inserted

Array implementation of stacks

- To implement a stack, items are inserted and removed at the same end (called the **top**)
- Efficient array implementation requires that the top of the stack be towards the center of the array, not fixed at one end
- To use an array to implement a stack, there is need of both the array itself and an integer
 - The integer tells:
 - Which location is currently the top of the stack, or
 - How many elements are in the stack

Pushing and popping

- If the **bottom** of the stack is at location 0, then an empty stack is represented by $top = -1$ or $count = 0$
- To add (**push**) an element, either:
 - Increment top and store the element in $stk[top]$, or
 - Store the element in $stk[count]$ and increment $count$
- To remove (**pop**) an element, either:
 - Get the element from $stk[top]$ and decrement top , or
 - Decrement $count$ and get the element in $stk[count]$

Error checking

- There are two stack errors that can occur:
 - **Underflow**: trying to pop (or peek at) an empty stack
 - **Overflow**: trying to push onto an already full stack
- For underflow, an exception is thrown
 - If the catch missed, Java will throw an `ArrayIndexOutOfBoundsException` exception
- For overflow, same things can be done
 - Or, user can check for the problem, and copy everything into a new, larger array

Linked-list implementation of stacks

- Since all the action happens at the top of a stack, a singly-linked list (SLL) is a fine way to implement it
- The header of the list points to the top of the stack

- Pushing is inserting an element at the front of the list
- Popping is removing an element from the front of the list

Linked-list implementation details

- With a linked-list representation, overflow will not happen (unless you exhaust memory, which is another kind of problem)
- Underflow can happen, and should be handled the same way as for an array implementation
- When a node is popped from a list, and the node references an object, the reference (the pointer in the node) does *not* need to be set to **null**

Array implementation of queues

- A **queue** is a first in, first out (**FIFO**) data structure
- This is accomplished by inserting at one end (the **rear**) and deleting from the other (the **front**)

- **To insert:** put new element in location 4, and set **rear** to 4
- **To delete:** take element from location 0, and set **front** to 1

Array implementation of queues

- Now the array contents “crawl” to the right as elements are inserted and deleted
- This will be a problem after a while.

Circular arrays

- We can treat the array holding the queue elements as circular (joined at the ends)

- Elements were added to this queue in the order 11, 22, 33, 44, 55, and will be removed in the same order
- Use: $\text{front} = (\text{front} + 1) \% \text{myQueue.length};$
and: $\text{rear} = (\text{rear} + 1) \% \text{myQueue.length};$

Full and empty queues

- If the queue were to become completely full, it would look like this:

- If we were then to remove all eight elements, making the queue completely empty, it would look like this:

This is a problem!

Full and empty queues: solutions

- **Solution #1:** Keep an additional variable

- **Solution #2:** (Slightly more efficient) Keep a gap between elements: consider the queue full when it has $n-1$ elements

Linked-list implementation of queues

- In a queue, insertions occur at one end, deletions at the other end
- Operations at the front of a singly-linked list (SLL) are $O(1)$, but at the other end they are $O(n)$
 - Because user have to find the last element each time
- BUT: there is a simple way to use a singly-linked list to implement both insertions and deletions in $O(1)$ time
 - User always need a pointer to the first thing in the list
 - User can keep an additional pointer to the *last* thing in the list

Adding a node

To **enqueue** (add) a node:

Find the current last node

Change it to point to the new last node

Change the **last** pointer in the list header

Removing a node

- To **dequeue** (remove) a node:
 - Copy the pointer from the first node into the header

Queue implementation details

- With an array implementation:
 - There are both overflow and underflow
 - Deleted elements should be set to **null**
- With a linked-list implementation:
 - only underflow
 - overflow is a global out-of-memory condition
 - there is no reason to set deleted elements to **null**
